1.0 INTRODUCTION

This completion report summarizes the remediation of the Star Rock Stockpile (the stockpile) site within the Hanover and Whitewater Creeks Investigation Unit (HWCIU) under an Interim Remedial Action (IRA) pursuant to the Administrative Order on Consent (AOC) for Freeport-McMoRan Chino Mines Company (Chino). This work was performed in accordance with the IRA Plan described in letters from Chino to the New Mexico Environment Department (NMED) dated April 27, 1998 and May 12, 1998.

Chino regraded and covered the stockpile material during construction of Reservoir 17 in 1998. NMED approved the interim action in a letter dated May 22, 1998.

The stockpile material was characterized in 1998 as part of the Phase 2 Comprehensive Groundwater Characterization Study (CGCS; Chino, 1998). This report describes that previous characterization of the stockpile material and the recent characterization of the cover material and vegetative cover. A monitoring plan is also proposed to detect potential erosion, observe continued vegetation growth, and protect water quality.

This completion report is organized into the following sections:

- Section 2 states the purposes of the IRA.
- Section 3 contains the site description and a brief history.
- Section 4 describes the characterization of the stockpile material and the regrading and covering performed in 1998.
- Section 5 describes the post-remediation characterization of vegetation and soil-cover materials.
- Section 6 provides a post-remediation monitoring plan for the site.
- Section 7 presents a summary.
- Section 8 contains references cited in this report.

2.0 INTERIM ACTION OBJECTIVES AND SCOPE OF WORK

The primary objective of the IRA was to reduce potential mass-loading of metals and acidity from source materials to surface water in accordance with New Mexico Water Quality Control Commission (WQCC) requirements under Regulation 1203. The IRA was conducted in accordance with the work plan Chino presented in a letter to NMED dated April 27, 1998, with additional information in a letter dated May 12, 1998, as a short- to intermediate-term solution to reduce migration of potentially affected runoff from entering Whitewater Creek. The IRA work plan was approved by NMED in a letter to Chino dated May 22, 1998.

Subsequent to the regrading and covering of the stockpile slopes, vegetation has colonized the cover material and erosion has stabilized, indicating the soil cover is capable of recruiting and maintaining a self-sustaining ecosystem suitable for wildlife habitat and/or grazing. The soil cover and vegetation was recently investigated to determine whether the interim action is consistent with long-term remediation goals. Regrading and covering the stockpile slopes, controlling surface-water runoff, and volunteer vegetation growing on the cover material have effectively reduced mass-loading from source materials and controlled potentially poor-quality discharges to surface water or groundwater resulting from past mining activities at the site.

The remedial action implemented at the Star Rock Stockpile is consistent with the following long-term remedial objectives:

- Reducing future releases to surface water, groundwater, and soil or sediment;
- Limiting direct exposure to the stockpile materials;
- Achieving post-mining land use;
- Preventing erosion; and
- Ensuring physical stability and site safety.

This interim action is also consistent with Chino's long-term strategy for closure/closeout and meets standards prescribed in the AOC agreement. It also conforms with the New Mexico Mining Act guidance pertaining to returning the disturbed area to a post-mining beneficial use, such as wildlife habitat or grazing.

3.0 BACKGROUND AND HISTORY

The Star Rock Stockpile is located on a hillside north of Whitewater Creek. It is on Chino property northeast of the town of Bayard, and west of the South Stockpile (Figure 1).

The Star Shaft is a vertical shaft accessing the northern underground mine workings of the historical Groundhog Mine. The Star Rock Stockpile is adjacent to, and north of Reservoir 17 and near several buildings used for mine operations (Figure 2). The stockpile material was generated from the early development of the underground workings and stockpiled in the vicinity of the shaft, and thus contains near surface non-acid generating rock material.

The bedrock geology in the area of the stockpile is predominately granodiorite. The stockpile footprint prior to remediation is shown in Figure 2. A portion of the prior stockpile surface is currently used by Chino for storage, haul truck traffic, and a rail spur used for operations at the Ivanhoe Concentrator. The southern slope of the stockpile was regraded and covered in 1998 during construction of Reservoir 17. Reservoir 17 is a flood-control structure constructed as an NMED requirement to renew Discharge Permit 526 (DP-526) at that time. During construction, some sediments in Whitewater Creek and some waste rock were removed to the West Stockpile, the slopes of the Star Rock Stockpile were regraded, and un-impacted sediments excavated from the reservoir footprint were used to cover the regraded slopes.

The stockpile material was characterized in 1998 for the Phase 2 Comprehensive Groundwater Characterization Study (CGCS; Chino, 1998). The stockpile was determined to be non-acid generating. Leach testing at that time indicated that the stockpile material did not leach concentrations of constituents in excess of WQCC standards. The Phase 2 CGCS characterization of the stockpile is summarized in Section 4.1.

The stockpile cover was not seeded, but vegetation has colonized the cover over the years, including grasses, forbs, shrubs, and trees.

4.0 STOCKPILE CHARACTERIZATION AND REMEDIATION

The Star Rock Stockpile was characterized, covered, and revegetated in 1998 as an interim remedial action under the AOC. Implementation of an IRA was accelerated to accommodate use of material excavated during construction of Reservoir 17 for a soil cover and to control erosion adjacent to the new reservoir.

Remediation objectives require reducing erosion associated with overland runoff and concentrated flows from high-intensity storm events. In addition to reducing potential mass-loading as described in Section 2.0, a secondary goal was to provide a stable surface that enhances vegetation growth and allows the establishment of a self-sustaining ecosystem. Characterization of the stockpile was performed at the same time the covering of the slopes was underway in order to assess the nature of the material before it was covered. Stockpile characterization and slope stabilization are described in the following sections.

4.1 Stockpile Material Characterization

The exposed stockpile surface was noted to be slightly mineralized, with visual observation of pyrite and iron staining (Chino, 1998). Stockpile characterization was performed by Daniel B. Stephens and Associates, Inc., in 1998. The investigation is detailed in the Phase 2 CGCS Report (Chino, 1998) and summarized in this section.

Fifteen samples were collected from test pits on the top of the stockpile in June 1998 (Figure 2). At the time of sampling, the western portion of the slope had been regraded and covered. Samples were collected from test pits excavated 1 to 2 feet into the surface of the stockpile by backhoe. The samples were composited by stockpile quadrant into four samples designated Star Rock NE, NW, SE, and SW.

The four composite samples were sent to SVL Analytical (SVL) in Kellogg, Idaho, for analysis of acid-base accounting (ABA), paste pH, total metals and general chemistry concentrations, and Synthetic Precipitation Leaching Procedure (SPLP) constituents.

The results of ABA tests are listed in Table 1. The Phase 2 CGCS classified the Star Rock Stockpile as not acid generating based on the net neutralization potential values of 392 to 630 tons of calcium carbonate per 1,000 tons. The data can also be compared to criteria in Price (1997) for acid-neutralization potential (ANP) to acid-generating potential (AGP) ratios. An ANP/AGP value of greater than 4 is classified as not acid generating. The composite samples from the stockpile had ANP/AGP values ranging from 14.8 to 202.2,

indicating they are not acid generating. This is further supported by the paste pH values of 7.5 to 7.6 standard units (su).

Total metals and SPLP results are listed in Tables 2 and 3, respectively. Total metals analysis was conducted to determine the chemical nature of the stockpile material. SPLP testing was performed to determine whether metals identified by total metals analysis had the potential to leach from the stockpile. One of the four composite samples had an elevated fluoride concentration possibly due to the high limestone content of the stockpile. Other metals were detected in the leachate, but not at elevated concentrations. The majority of concentrations were less than the analytical detection limits.

4.2 Stockpile Slope Regrading and Runon Controls

During the 1998 excavation of Reservoir 17, adjacent to the Star Rock Stockpile, sediments from Whitewater Creek were removed and hauled to the West Stockpile. Bedrock was also excavated from below the channel sediments to provide additional capacity in the reservoir. This excavated bedrock material was tested for paste pH during excavation. Bedrock material with a paste pH of 5 su or less was also placed at the West Stockpile. Excavated material with a pH of greater than 5 su was placed on the regraded Star Rock Stockpile slopes as a soil cover and allowed to revegetate by volunteer vegetation.

The area of interim remedial action is shown in Figure 2, and includes the south slopes of the stockpile that are not used in operational areas for storage, rail spurs, or haul traffic. The area was regraded to flatten the slopes to allow placement of the soil cover. Slope steepness measured in 2010 ranged from an average 2.6 horizontal to 1 vertical (2.6H:1V) on the eastern portion of the slope to 2.3H:1V on the western portion. The slope length ranges from approximately 110 to 160 feet. The slopes are slightly steeper at the toe due to a bedrock cut along the lower railroad track.

An earthen berm is located along the crest of the slope to divert surface-water runoff from the haul road and storage areas away from the slope, thereby reducing the potential for erosion of the cover material.

5.0 POST-REMEDIATION CHARACTERIZATION

In 2010, Chino and Golder inspected Star Rock Stockpile to determine the success of the volunteer vegetation on the soil cover, and the suitability of the soil cover as a long-term interim action consistent with Chino's long-term remediation goals.

5.1 Vegetation Inspection

The vegetation inspection consisted of a visual survey of the reclaimed slope to evaluate the progress of plant establishment and to determine if the vegetation is viable, self-sustaining, and capable of supporting the post-mining land use of wildlife habitat and/or grazing. During the inspection, canopy cover and shrub densities were estimated at each site and plant species were identified. Golder completed and documented the survey, which was included in the Groundhog Annual Report and is attached here as Appendix A.

The stockpile was inspected on September 30, 2010, at the end of the summer monsoon season. Originally covered in 1998, the area was not seeded, but native plants have colonized the site. The plant community is in very good condition with an estimated average canopy cover of 45% and an estimated shrub density of 350 stems per acre. A total of 18 species were identified in the plant community, including grasses, forbs, shrubs, and trees (Table 4). This indicates that the soil cover is capable of recruiting and maintaining vegetation that is viable and self sustaining.

5.2 Cover Material Characterization

The success of the vegetation on the former stockpile is an indication that the soil-cover material is performing well as a growth medium. Additional characterization of the soil-cover material was performed to measure the cover thickness and to determine if the cover material is consistent with the 1996 Mining and Minerals Division (MMD) Draft Closeout Plan guidelines (MMD, 1996).

5.2.1 Field Investigation

The December 2010 field investigation included excavating and sampling test pits, measuring slope angles, visually inspecting the cover material lithology, and inspecting the slope toe for evidence of groundwater seepage.

Three test pits were excavated in the stockpile during December 2010 to investigate the thickness of the cover and suitability of the cover material as a growth medium. Test pit locations were surveyed using a hand-held Global Positioning System unit and are shown

on Figure 2. Test pits were excavated by James Hamilton Construction Company using a trackhoe. The test pits were each excavated to a depth of 4 feet and logged in the field according to the Unified Soil Classification System (USCS). The volume and lithology of rock fragments over 2 millimeters (mm) in the soil cover was also estimated in accordance with the United States Department of Agriculture (USDA) method for classifying soils (Table 5). Detailed logs for the test pits are in Appendix B.

Samples were collected from the cover material in each test pit. Oversized materials (larger than 1 inch) were excluded from the sample material. Samples were collected by hand using clean nitrile gloves for each sample. No samples were collected from the underlying stockpile materials, but the material was visually described (Appendix B). Approximately 1 gallon of material was collected from each test pit, placed in a clean plastic Ziplock bag, and labeled with the sample identification number, the date and time collected, and the sampler's initials. Samples were packaged and shipped to Energy Laboratories in Helena, Montana, for analyses.

The surface of the cover was visually inspected and described. Slope angles were measured from the crest and toe using an Abney level.

5.2.2 Laboratory Analysis

The bulk soil samples were air-dried and passed through a 2-mm sieve at the laboratory. The less than 2-mm fraction was analyzed for:

- Texture (Method ASA15-5),
- Saturation percentage (Method USDA27-A), and
- Saturated paste pH and electrical conductivity (EC; Method ASAM10-32).

The laboratory was instructed to also run ABA with sulfur forms (Modified Sobeck) if the paste pH values were less than 5 su. Laboratory data sheets are in Appendix C.

5.2.3 Result of the Cover Material Investigation

The three test pits showed a generally consistent cover thickness of 6 inches. Test pit SR-TP-1 (Figure 2) had a slightly thinner cover of approximately 4 inches. However, the cover thickness was irregular, with an undulating contact with underlying stockpile materials. The soil cover varied from 4 inches thick to 12 inches thick in all three test pits. The USCS classification of the soil-cover material is a silty clay with gravel, and the USDA classification is a loam to a sandy loam. The cover contained moderately dense roots,

which also grew into the stockpile material, indicating that plants are utilizing the stockpile material as a growth medium.

The underlying stockpile material matrix was similar in texture and color to the soil cover in test pits SR-TP-1 and SR-TP-2 (Table 5 and Figure 2), and the contact was gradational in areas, indicating some mixing of the stockpile and cover materials. Underlying stockpile material in these two pits was a loose, dry, clayey gravel with sand. Stockpile material from test pit SR-TP-1 had clasts occurring in lenses of mixed limestone/granodiorite and granodiorite with some iron oxide staining. The stockpile material from test pit SR-TP-2 had clasts of primarily limestone to 3 feet deep, and mixed with granodiorite below 3 feet. The soil cover and underlying stockpile material reacted strongly with hydrochloric acid, indicating the presence of calcium carbonate in the soil and stockpile matrix. No sulfide mineralization was observed.

Test pit SR-TP-3, on the western end of the stockpile (Figure 2), had similar waste rock (clayey gravel with sand), but was slightly cemented and moist. Clasts were primarily limestone with minor granodiorite and shale. The soil cover and underlying stockpile material reacted strongly with hydrochloric acid, indicating the presence of calcium carbonate in the soil and stockpile matrix. No sulfide mineralization was observed.

Over the surface of the stockpile, coarse rock fragments were concentrated on the top of the cover by settling and deflation over time, creating a rock armor. The angular rock fragments ranged from gravel to occasional fragments larger than 1 foot. The lithology of the rock fragments was primarily granodiorite with some porphyry stock. Scattered sandstone fragments and occasional magnetite cobbles were also observed. The presence of these coarse fragments is desirable from an erosional stability perspective.

Tables 5 summarizes the description of the soil-cover samples collected from each test pit, including the percent volume of rock fragments. Table 6 lists the laboratory results for texture, saturated paste pH and EC, and saturation percentage for each sample. Based on the MMD Draft Closeout Plan guidelines (MMD, 1996), the results indicate that the soil-cover material is suitable for use as a growth medium.

The lack of sulfide mineralization and paste pH results of 7.2 to 7.3 demonstrate that the soil-cover material has not generated acidity even though it has been exposed at the surface for over 12 years. Similarly, the underlying stockpile material has paste pH values of 7.5 to 7.6 su, and is not acid generating. The well-established, colonized vegetation and presence of roots in the cover and stockpile materials demonstrate that the cover material and the underlying stockpile material are supporting plant growth.

Slope steepness ranges from an average 2.6H:1V on eastern portion of the slope to 2.3H:1V on the western portion. The slope length ranges from 110 to 160 feet. The bedrock outcrop at the toe shows cover material over the bedrock, with no exposed stockpile material. No evidence of seepage was seen at the soil-cover/bedrock interface.

6.0 POST-REMEDATION MONITORING

This section presents the post-remediation monitoring plan for Star Rock Stockpile. The plan includes erosion and vegetation monitoring of the soil cover. The site will remain under the oversight of the Chino AOC at least until the Record of Decision for the HWCUI has been approved by NMED. Monitoring may then be included as part of the long-term closure actions for Chino under DP-1340. Surface-water monitoring is not proposed for this facility because the amount of runoff from the small area would be impractical to capture and sample.

Vegetation and erosion will be monitored until a self-sustaining vegetated cover is established for grazing or wildlife habitat post-mining land use. The stockpile is in proximity to operational areas (roads and active pipelines), and could be used again for operations, but will be monitored until that time as a closed facility.

The area will be monitored as follows: The revegetated soil cover and surface-water controls will be visually monitored for erosion and vegetation success annually for 4 years. The vegetation survey will present the data in a format comparable to the Vegetation Success Standards and Success Monitoring Section of Appendix C in the MMD revision 01-1 To Permit GR000RE, including canopy cover, shrub density, and plant diversity. Results of the vegetation survey will be submitted as part of the Groundhog Mine Site annual report. Surface-water controls and erosion will be visually observed quarterly until vegetation surveys demonstrate that the site is stable.

7.0 SUMMARY

The Star Rock Stockpile was remediated with a soil cover that supports vegetation. The IRA was conducted in accordance with the NMED-approved interim action as documented in the administrative record as described in Section 1.0.

Stockpile material was regraded and covered on the southern slopes of the stockpile on the hillside above Whitewater Creek in 1998, during construction of Reservoir 17. Cover material was excavated from the footprint of Reservoir 17, and placed back on the regraded stockpile if the pH was greater than 5 su. A surface-water control berm was built at the crest to prevent surface-water runoff, thereby reducing the potential for erosion on the covered slope. The soil cover was subsequently colonized by natural vegetation and is now supporting a diverse plant community.

Results of the field investigation of the soil cover indicate that it is approximately 6 inches thick and mixed with the underlying stockpile materials to some degree. The stockpile material is primarily limestone and mixed limestone/granodiorite. The soil-cover and stockpile material both react with hydrochloric acid, indicating the presence of calcium carbonate. The roots from the vegetation in the soil cover extend into the stockpile material. The well-established, colonized vegetation and presence of roots in the cover and stockpile materials demonstrate that the cover material and the underlying stockpile material are supporting plant growth.

Results of the field investigation and laboratory analyses indicate that the soil cover and underlying stockpile material are providing a suitable long-term growth medium. The coarse texture of the soil cover at the surface reduces erosion, and no seepage has been observed at the toe of the stockpile slope.

Vegetation is established, erosion and sedimentation are reduced, and the land can be designated for a variety of uses, in line with success criteria of the Closure/Closeout Plan for Chino.

APPENDIX A
VEGETATION INSPECTION
SEPTEMBER 2010

Date: October 28, 2010**To:** Pam Pinson**Project No.:** 103-92704**Company:** Freeport-McMoRan Chino Mines
Company**From:** Doug Romig**cc:** Jen Pepe
Ned Hall**Email:** dromig@golder.com**RE: 2010 VEGETATION INSPECTION OF THE RECLAMATION AT THE GROUNDHOG MINE
AND SMALL HISTORIC STOCKPILE SITES**

1.0 INTRODUCTION

Freeport-McMoRan Chino Mines Company (Chino) completed reclamation of several small waste rock stockpiles in the headwaters of Whitewater Creek in 2004, and the Groundhog mine site in 2008. This work fulfilled the mitigation requirements under Interim Remedial Actions (IRAs) pursuant to the Chino Administrative Order on Consent (AOC) between Chino and the New Mexico Environment Department (NMED).

The project site is approximately 1-½ miles northeast of Bayard, New Mexico. The Groundhog mine site is located on the flanks of San Jose Mountain in a small canyon upgradient of Whitewater Creek along the Lake One haul road. Collectively known as the Small Stockpiles, the historic Osceolla, CG Bell, and Tenderfoot B sites reside along the banks and steep hillsides immediately above Whitewater Creek. The Star Rock Stockpile, located across the Whitewater Creek drainage from the Tenderfoot B, was also included in the 2010 annual inspection, although it is not specifically included in an IRA under the AOC. Figure 1 illustrates the general locations of these sites. Reclamation at these five sites included the removal of potentially-reactive stockpile materials and affected soils, closure of mine openings, site regrading, cover placement, and revegetation of the removal and borrow areas. This work was performed as part of the IRAs to reduce mass loading of metals and acidity to groundwater and surface water.

This technical memorandum documents the vegetation inspection for the Groundhog Mine and Small Stockpile reclamation sites for 2010. The sites were inspected to assess the general condition of the reclamation, estimate vegetation cover, and document the plant species that occur. The area was inspected on September 30, 2010 by Mr. Douglas Romig and Ms. Jen Pepe of Golder Associates Inc. (Golder). Also present during the inspection was Ms. Pam Pinson (Chino) and Mr. Phil Harrigan (NMED).

2.0 VEGETATION MONITORING

The vegetation inspection consisted of a foot survey of the reclaimed areas and cover borrow sites to evaluate the progress of plant establishment and determine if the vegetated cover is viable, self-sustaining and capable of supporting the post-mining land use of wildlife habitat and/or grazing. During

the inspection, canopy cover and shrub densities were estimated at each site and plant species were identified. A summary of the general conditions at each site is provided below. Photo documentation of the site conditions are provided in the photo log attached to this document. In addition, Table 1 provides a list of plant species identified during the 2009 and 2010 inspections at the Groundhog Mine and Small Stockpile sites.

2.1 Tenderfoot B

The Tenderfoot B site was hand seeded in 2004 by Chino staff and currently supports a diverse and robust plant community (Photos A through C). Average canopy cover was estimated at 75 percent. Shrubs were numerous (150 stems/acre) and at comparable densities to the adjacent native areas. In addition, numerous native forbs have become established. A total of 31 species have been identified in the reclaimed plant community (Table 1). The majority of these species were not in the reclamation seed mix and have been recruited from the native plant community adjacent to the site. A small rill was observed in the midslope position at the site, though it appeared to be inactive because perennial plants are becoming established in the small channel (Photo D).

2.2 CG Bell

The CG Bell site was also hand seeded in 2004 and vegetation establishment is discontinuous across the site (Photos E through H). Average canopy cover was estimated at 15 percent across the site and 10 species were identified in the revegetated plant community (Table 1). The site has been successful at recruiting two native shrub species from adjacent undisturbed areas. Shrub density was estimated at 150 stems/acre which is considered good at this stage of the reclamation. The site has also recruited numerous forb species but does not yet support an understory of grasses.

2.3 Osceolla

The Osceolla site extends from Whitewater Creek along the railroad tracts to an access road to the north. Establishment of vegetation at the Osceolla site is inconsistent across the site. Vegetation is becoming established along the railroad tracks and in the east and west portions of the site. Estimated canopy cover in these areas was 50 percent (Photos I through K). Central sections of the site are similar to the CG Bell site where vegetation has been slow to establish (Photo L). Twelve species were identified in the revegetated plant community (Table 1), the majority of these species were recruited from adjacent undisturbed areas. Shrub density is low, estimated at 50 stems/acre.

2.4 Star Rock Stockpile

The Star Rock Stockpile site was inspected at the request of Ms. Pinson. This stockpile was characterized in the late 1990's along with the three Small Historic Stockpiles and lab analysis determined that this site did not exceed New Mexico groundwater standards unlike the other 3 historic sites. Covered in 1997, the area was not seeded, and native plants have colonized the site. The plant community is in very good condition with an estimated average canopy cover of 45% and an estimated shrub density of

350 stems/acre (Photos M and N). A total of 18 species were identified in the reclaimed plant community (Table 1).

2.5 Groundhog Mine

The Groundhog site was hydroseeded by Freeport-McMoRan Reclamation Services in 2008. Vegetation establishment at the Groundhog Mine site is progressing exceptionally well based on qualitative assessments of cover, density, and diversity. Across the reclaimed area, average canopy cover was estimated at 50 percent (Photos O through R). These cover values exceed the levels typical for the early establishment phase of reclamation in the region.

The Groundhog reclamation has excellent diversity. Eleven additional plant species were identified this year bringing the total to 46 species that have been found in the reclaimed area in the past 2 years (Table 1). While some weedy annuals were present in the reclaimed areas, they were not widespread and no noxious weeds were identified. Average shrub density was estimated around 50 stems/acre.

The vegetation in the borrow area at the Groundhog site is generally progressing well (Photos S and T). Plant density exceeds one plant per square foot and is considered appropriate for this stage in the reclamation. Small areas of localized rill erosion were observed in several locations across the borrow area. Many of these rills areas appear to initiate in undisturbed areas upgradient of the borrow site and represent the formation of a natural incipient drainage pattern along the lower slopes.

3.0 SUMMARY AND RECOMMENDATIONS

In general, revegetation efforts have been successful at the Groundhog and Small Stockpile sites, and the majority of the areas disturbed now support robust and diverse plant communities and soil surfaces are stable. Small areas at both the CG Bell and Osceolla sites appear to have had poor germination and/or seedling establishment, though they continue to recruit volunteer species from native areas. Moreover, it was noted that more species were identified at each reclaimed site relative to the 2009 inspections. This would indicate that these areas are capable of maintaining a vegetated cover that is viable and self-sustaining. Finally, the Star Rock Stockpile demonstrates that these types of sites are capable of recruiting volunteer vegetation over the long term.

Golder recommends continued annual qualitative monitoring of the vegetation progress of these areas. When all the sites have achieved cover levels that are considered adequate, Golder will complete a formal quantitative survey of the areas to demonstrate that the vegetation has achieved the success targets consistent with the Vegetation Success Standards of Appendix C in the Mining and Minerals Division revision 01-1 to Permit GR000RE.
